July 2019

Abstract

This study investigates the effect of violent crime on school district-level achievement in English Language Arts (ELA) and Mathematics. The research design exploits variation in achievement and violent crime across 813 school districts in the United States and seven birth cohorts of children born between 1996 and 2002. The identification strategy leverages exogenous shocks to crime rates arising from the availability of federal funds to hire police officers in the local police departments where the school districts operate. Results show that children who entered the school system when the violent crime rate in their school districts was lower score higher in ELA by the end of eighth grade, relative to children attending schools in the same district but who entered the school system when the violent crime rate was higher. A 10 % decline in the violent crime rate experienced at ages 0-6 raises eighth-grade ELA achievement in the district by .03 standard deviations. Models that estimate effects by race and gender show larger impacts among black children and boys. The district-wide effect on Mathematics achievement is smaller and statistically non-significant. These findings extend our understanding of the geography of educational opportunity in the United States and reinforce the idea that understanding inequalities in academic achievement requires evidence on what happens inside schools as well as what happens outside of schools.

The author thanks Sean Reardon, Patrick Sharkey, participants at the Furman Center Fellows Meetings, and participants at the Russell Sage Foundation conference “Improving Education and Reducing Inequality in the United States: Obtaining New Insights from Population-Based Academic Performance Data” for helpful comments. Findings from this study have been presented at the 2017 Fall Research Conference of the Association for Public Policy Analysis and Management in Chicago, the 2018 Annual Meeting of the Population Association of America in Denver, and the Spring 2019 Conference of the Society for Research on Educational Effectiveness in Washington, DC. This research has been supported by a grant from the Russell Sage Foundation and the William T. Grant Foundation (RSF Award: 83-17-07).

Recent work by Reardon et al. (2016a) has reported large disparities in academic achievement levels and in racial/ethnic achievement gaps across school districts in the United States. Whereas the mean achievement in school districts like Brookline, MA and Cupertino, CA is three grades above the national mean, the mean academic achievement in Camden, NJ and Detroit, MI is more than two grades below the country average. Similarly, the white-black achievement gap ranges from virtually zero in places like Hillside, NJ to more than one standard deviation in Cleveland, OH and Atlanta, GA. Correlational evidence suggests that variation in mean achievement levels is highly related to the socioeconomic characteristics of the families living in the school district (Reardon, 2016), and that racial/ethnic gaps are wider in school districts with higher levels of racial/ethnic segregation and larger racial/ethnic differences in parental income and education levels (Reardon et al., 2016a).

By themselves, these findings have made a groundbreaking contribution to our understanding of how geography shapes educational opportunity in the United States. However, our knowledge of the causal mechanisms underlying these patterns is more limited. Building on an extensive body of ethnographic and quantitative evidence showing that exposure to violent crime is a key pathway through which growing up in disadvantaged neighborhoods affects children’s developmental trajectories (Burdick-Will et al., 2011; Harding, 2009; Harding et al., 2011; Sharkey, 2018a), this study aims to fill this gap by examining how changes in violent crime in the school districts where children grow up shape their academic achievement.

The study combines multiple sources of aggregated school district-level data to estimate the impact of violent crime experienced in childhood (at ages 0 to 6) on English Language Arts (ELA) and Mathematics eighth-grade achievement in 813 school districts in the United States and seven birth cohorts of children born between 1996 and 2002. During these seven years, the violent crime rate fell by 23 % nationally, and in school districts like Chicago and New York, the decline in violent crime over that period was greater than 35 %.

To produce causal estimates of the effect of violent crime on achievement, the research

design leverages exogenous shocks to crime rates arising from the availability of funds to hire police officers in local police departments through the Community Oriented Policing Services (COPS) grants program. This program substantially increased the size of police departments that received the grants, which led to important reductions in violent crime rates (Evans and Owens, 2007). Here, I extrapolate this finding to an instrumental variable setup in which I exploit the change in the violent crime rate that was induced by the COPS grants to recover the causal effect of violent crime on achievement.

The findings show that birth cohorts who experienced lower levels of violence during childhood perform better in ELA by the end of eighth grade, relative to older birth cohorts of the same school district who experienced higher violent crime rates in childhood. A 10 % decline in the violent crime rate raised the district-wide performance in ELA by .03 standard deviations. Analyses by race/ethnicity and gender show that the benefits of declining violence are larger among black students and males. Models exploring the effect of violent crime on Mathematics achievement also suggest performance improvements as crime rates fell, but those effects are smaller and concentrated among boys. Supplementary analyses indicate that the effect of crime on achievement is not driven by compositional changes in school districts or by changes in school district revenue and spending after the receipt of the COPS grants.

This article also contributes to the literature on the consequences of the decline in violence in America. The study is situated in the late 1990s and early 2000s, a period when community violence fell sharply across the country. Between 1991 and 2015, the property crime rate fell by 50 %, the violent crime rate fell by 51 %, and the homicide rate fell by 54 % across the nation (United States Department of Justice, 2015).¹ In cities like New York or Los Angeles, the decline in the murder rate between the highest record in the 1990s and

¹Work by Lauritsen et al. (2016) shows a discrepancy between crime trends in the UCR data and in the National Crime Victimization Survey (NCVS). Their findings suggest that NCVS data are more reliable indicators of the trends in violent crime from 1973 to the mid-1980s. Given the time period being studied here, 1996 to 2008, the UCR data provide an accurate account of how crime rates changed over time and across space.

the level in 2015 was larger than 75 %. Even cities that still today struggle with severe problems of community violence like Chicago and Detroit have experienced reductions in their murder rates of at least 30 % between 1991 and 2015.² This progress in making cities safer represents one of the most remarkable improvements in the quality of life in urban America in recent history (Sharkey, 2018b), and while the literature has made a lot of progress in documenting the causes of this decline (Levitt, 2004; Zimring, 2006), much less is known about its consequences for individuals and communities. This study aims to fill this gap by documenting how the school achievement of children who lived through the decline in violence has changed as their communities became safer.

Neighborhood Violence and Educational Outcomes

A long tradition of scholarship in criminology, economics, and sociology has documented the negative consequences of growing up in violent neighborhoods (Aizer, 2007; Burdick-Will, 2013; Burdick-Will et al., 2011; Harding, 2009; Harding et al., 2011; Sharkey, 2018a). Studies examining the acute, short-term effects of exposure to neighborhood violence have found that when children take cognitive assessments in the days after a homicide has occurred in their neighborhood, their performance declines relative to other children from the same neighborhood who were not exposed to violence in the days before the assessments were given (Sharkey, 2010; Sharkey et al., 2014). Evidence on non-cognitive outcomes among children shows that concentration, self-regulatory behaviors, cortisol levels, and sleeping patterns are severely affected in the aftermath of a violent crime (Heissel et al., 2017; McCoy et al., 2015; Sharkey et al., 2012).

In addition to the consequences of direct exposure to violent crime, ethnographic studies have shown that children living in disadvantaged neighborhoods are forced to develop strategies to navigate threatening public spaces and change their daily routines and

²Baltimore and Milwaukee cannot join Chicago and Detroit on that list because of the spike in crime that they experienced in 2015, which brought the murder rate above the level in 1991. If changes are measured between 1991 and 2014, Baltimore and Milwaukee had reductions in their murder rates of 18 and 44 %, respectively.

patterns of social interaction in a way that may negatively affect their educational development (Shedd, 2015). Adolescents from disadvantaged and violent neighborhoods interact more frequently with older peers who provide them not only with street wisdom and safety, but also with alternative scripts and frames that shape their attitudes toward schooling (Harding, 2010). Boys and girls living in dangerous neighborhoods are forced to develop a reputation for being “tough” (Anderson, 2000; Jones, 2009), and although earning this reputation may prevent them from being victimized in the streets, it may complicate their interactions with teachers and school staff and affect their academic performance (Devine, 1996).

Beyond these effects on individuals, an extensive literature in criminology and urban sociology has documented the negative effects that crime has at the community level. Neighborhood violence undermines the quality of life in entire communities, transforms the socio-demographic composition of neighborhoods, and leads to public and private disinvestment (Morenoff and Sampson, 1997; Sampson, 2012; Skogan, 1986). Recent evidence on these community-level effects of crime has shown that children born to low-income families experience lower levels of economic mobility if violent crime is higher in the county where they spend their adolescence (Sharkey and Torrats-Espinosa, 2017).

One of the most distinct features of neighborhood violence in the United States is its degree of spatial concentration in low-income and minority neighborhoods. Evidence from crime trends in micro-places within neighborhoods in Boston shows that the majority of robberies and gun violence incidents across the city take place in a very small fraction of street segments and intersections (Braga et al., 2010; Braga et al., 2011). This high degree of spacial concentration and the high levels of residential racial segregation that characterize American cities generate large disparities in exposure to violence across different racial groups. Using data from the Uniform Crime Reports program, Sharkey (2018a) estimates that the homicide victimization rate for blacks is 6.6 times higher than for whites. Estimates from self-reports of violent victimization and nonfatal firearm victimization also show large black-

white gaps. These same data sources reveal large gender disparities in exposure to violence. The homicide victimization rate for males is 3.9 times higher than for females, and the rates of self-reported violent victimization and nonfatal firearm victimization are also much higher among males.

These studies show that crime is a salient attribute of children’s environment that reaches beyond individuals who are directly victimized (Sharkey, 2018a). The spatial concentration of crime disrupts the functioning of communities, lowers the quality institutions such as schools, and erodes the quality of resources that facilitate academic success. Building on this body of evidence, this study pushes the literature forward and takes a national perspective in the study of the long-term effect of crime on children’s academic performance.

Data Description

The selection of school districts begins with the 1,000 school districts with the largest student enrollment in grades 3-8 in school year 2008-2009. Districts included in the sample are those that have data on academic achievement in eighth grade for black, Hispanic, and white children and crime data when children of each birth cohort were 0-6 years old. The analytic sample includes 813 unique school districts that yield an unbalanced panel of 4,255 school district-cohort observations.³

Data on academic achievement are obtained from the Stanford Education Data Archive (SEDA). The SEDA data include estimates of the average test scores of students in virtually all public school districts in the United States (Reardon et al., 2016b). The estimates are obtained from approximately 300 million state accountability tests taken by approximately 45 million students in grades 3 to 8 attending public and charter schools between school years 2008-2009 and 2014-2015, which represent most of all third to eighth graders attend-

³Among the 813 school districts, 59 have data on eighth-grade achievement for two birth cohorts, 85 have data on eighth-grade achievement for three birth cohorts, 100 have data on eighth-grade achievement for four birth cohorts, 148 have data on eighth-grade achievement for five birth cohorts, 205 have data on eighth-grade achievement for six birth cohorts, and 216 have data on eighth-grade achievement for seven birth cohorts. All findings remain qualitatively the same if the analyses are restricted to the 216 school districts for which data for the seven birth cohorts are available.

ing public and charter schools at that time.⁴ Test scores are placed on a common scale that allows performance to be compared across school districts, states, grades, and years. The achievement measures in the SEDA data are disaggregated by grade (3 to 8), school year (2008-2009 to 2014-2015), subject (ELA and Mathematics), race/ethnicity (Asian, black, Hispanic, and white), and gender.⁵ This study focuses on the overall achievement in the district, achievement by race and ethnicity (black, Hispanic, and white students), and achievement by gender (females and males). All measures of achievement are in standard deviation units of the national distribution.

The SEDA data are repeated cross-sections of achievement by grade and school year, thus enabling the possibility of studying the trajectory of several birth cohorts. As stated before, the data include achievement measures in grades 3-8 for school years 2008-2009 to 2014-2015. This means that there are 12 birth cohorts represented in the SEDA data, although not all cohorts have achievement measures in all grades. Assuming that children begin first grade at the age of 6, children born in 1996 were in eighth grade in school year 2008-2009, and children born in 2007 were in third grade in school year 2014-2015. Under this assumption, eighth-grade estimates from school years 2008-2009 to 2014-2015 in the SEDA data can be used to characterize the educational achievement of children born between 1996 and 2002.

As noted in Reardon (2018), this operationalization of cohorts does not ensure that a consistent pool of students is followed over time. Students in eighth grade in school year 2014-2015 in a given district are not the exact same ones who were in third grade in school year 2009-2010 in the same district. Students moving to other school districts or being retained in a grade will change the pool of students between third and eighth grade. Without access to longitudinal student-level data, this limitation is impossible to address. In

⁴ School districts are defined according to the geographic catchment areas that include students in traditional public schools and local charter schools. Test scores from charter schools are included in the public school district in which they are chartered. For charter schools that are not chartered by a district, their test scores are included in the district in which they are physically located (Reardon, 2018).

⁵For additional details on the construction of aggregate measures from student test score data see Ho and Reardon (2012) and Reardon and Ho (2015).

additional analyses included in the Appendix, I show that enrollment figures and the racial composition of schools in the districts in the sample did not change in a way that threatens the validity of the results reported here.

Crime data are obtained from the FBI's Uniform Crime Report (UCR) program, which contain crimes known or reported to local police agencies. The main analyses will focus on the impact of changes in violent crimes (murders, aggravated assaults, and robberies). Crime is measured as the average crime rate in the school district when children of a given birth cohort were 0-6 years old.⁶ To obtain school district crime rates, I assign crime reports from local police agencies to municipalities (i.e., cities and towns) using the 2012 Law Enforcement Agency Identifiers Crosswalk (United States Bureau of Justice Statistics, 2018), and I crosswalk places to school districts by identifying the school district that contains the centroid of a given city or town.

Data on the COPS program are obtained from the Department of Justice,⁷ which include the number of full-time police officers that were hired through the grants program in each year. The instrument is constructed by computing the number of full-time officers per 100,000 residents that each local police department had received up to the year when a given birth cohort was 0-6 years old. Additional details about the instrument are provided in the next section.

Figure 1 shows the average eighth-grade achievement by birth cohort and racial/ethnic group in the districts in the sample. The bars reveal large achievement gaps across racial/ethnic groups. White students scored between .1 and .2 standard deviations above the eighth-grade

⁶The choice of focusing on exposure to crime at ages 0-6 is motivated by the research design, which exploits the availability of funds to hire police officers through the COPS program. The first phase of the COPS program, the one being considered in this study, ended in 2008, which is the year when the 2002 birth cohort was 6 years old. After 2008, the COPS program changed its rules for adjudicating grants, making the use of post-2008 data inadequate for the estimation strategy proposed here (see Mello (2019) for an analysis of the COPS program under the new grant allocation rule). Another reason to average crime rates over ages 0-6 is to obtain more stable crime rates. These multi-year averages also help in the 2SLS estimation by yielding a stronger first-stage. Figure A8 in the Appendix shows OLS results when the violent crime rate is measured in one-year windows from age 0 to age 13.

⁷The COPS data were collected by William Evans and Emily Owens, who generously shared them for this project.

national mean, Hispanic students scored between .3 and .5 standard deviations below the national mean, and black students scored between .4 and .5 standard deviations below the national mean. Table 1 shows means and standard deviations for violent crime rates at ages 0-6 for each of the seven birth cohorts in the study. The oldest cohort was 0-6 years old between 1996 and 2002 and experienced an average violent crime rate for that period of 880 crimes per 100,000 residents. The youngest birth cohort was 0-6 years old between 2002 and 2008 and experienced an average violent crime rate for that period of 800 crimes per 100,000 residents.

Table 1 also shows how COPS grants grew over time. On average, 16 police officers had been hired and 2.2 million dollars had been awarded for each 100,000 residents in the district when the 1996 birth cohort was 0-6 years old. When the 2002 birth cohort was 0-6 years old, these figures had increased to 28 police officers and 3.7 million dollars for each 100,000 residents in the district. Figure A1 in the Appendix shows that, in relative terms, more police officers were hired through the COPS program than outside of the program between 1996 and 2008, suggesting that the COPS program played an important role in increasing the size of police departments during the time considered in this study.⁸

Empirical Strategy

The empirical strategy exploits geographic variation in achievement and crime across 813 school districts and temporal variation across seven birth cohorts in a difference-in-differences framework. The estimating equation takes the following form:

$$Y_{sc} = \delta_{OLS} Crime_{sc} + \mathbf{S}'_s + \mathbf{C}'_c + \epsilon_{sc}. \quad (1)$$

In Equation (1), Y_{sc} is the eighth-grade ELA and Mathematics achievement in school district s for birth cohort c (measured in standard deviations of the national distribution),

⁸The minimum, median, and maximum number of police officers per 100,000 residents at ages 0-6 for the 1996 birth cohort were 0, 15.15, and 145.2. For the 2002 birth cohort, these figures were 0, 24.75, and 431.84.

$Crime_{sc}$ is the log average violent crime rate in school district s measured when birth cohort c was 0-6 years old, \mathbf{S}'_s is a set of school district fixed effects, \mathbf{C}'_c is a set of birth cohort fixed effects, and ϵ_{sc} is an stochastic error term. Standard errors are clustered by school district.⁹

The parameter δ_{OLS} characterizes the association between changes in crime rates at ages 0-6 and changes in achievement by the end of eighth grade. The two sets of fixed effects, \mathbf{S}'_s and \mathbf{C}'_c , will account for time-invariant attributes of the school district and time trends that are common to all districts. Although this difference-in-differences specification represents an improvement upon cross-sectional designs, causal identification will not be possible if within-district changes in crime rates over this period are endogenous. The next section discusses the implications of such scenario and proposes a strategy to deal with these endogeneity concerns.

Two-Stage Least Squares Estimation

Estimating the impact of exposure to violent crime on academic achievement presents a number of empirical challenges that are difficult to overcome without an experimental design. Neighborhood violence is highly correlated with other attributes of neighborhoods that may also have an impact on academic achievement, such as poverty and labor force participation (Aizer, 2007). One possibility would be to control for as many of these factors as the data allow, but the threat of having omitted one or more confounders would still be present. Another threat is the residential selection of families into school districts on the basis of socio-economic attributes that are predictive of academic performance (Sampson and Sharkey, 2008). If more affluent families have the ability to forecast changes in crime rates in their school district and decide to relocate to a safer school district, higher achievement levels in low-crime school districts could be a reflection of this sorting process.

⁹In a set of robustness tests, all OLS and 2SLS models are estimated including a vector of interpolated demographic controls, \mathbf{X}'_{sc} , measured for school district s when birth cohort c was 0-6 years old. These controls include % non-Hispanic white, % non-Hispanic black, % Hispanic, % foreign-born, % unemployed, % families with income below the poverty line, and median household income (in 2000 USD). All these demographics are computed by linearly interpolating between census years. All results remain the same when including these controls.

To deal with these endogeneity concerns and obtain causal estimates of the the impact of crime on achievement, I propose a Two-Stage Least Squares (2SLS) estimation strategy that leverages exogenous shocks to crime rates arising from the availability of funds to hire police officers in the local police departments where the school districts operate. Specifically, the 2SLS strategy exploits the timing of grants that law enforcement agencies received under the Community Oriented Policing Service (COPS) program. The COPS program was established in 1994 as part of the Violent Crime Control and Law Enforcement Act. Through the COPS Universal Hiring Program, police departments that applied for grants received funding to cover 75 % of the cost of hiring and re-hiring entry-level career law enforcement officers. By end of fiscal year 2004, the COPS program had distributed \$11.3 billion in grants, with \$5 billion of these funds being spent to hire 64,000 new police officers (Evans and Owens, 2007). By 2016, the COPS program had distributed approximately \$14.9 billion in grants across 13,000 law enforcement agencies (Office of Community Oriented Policing Services 2017).

Evans and Owens (2007) showed that the addition of police officers through the COPS grants program had a causal effect on violent and property crimes between 1990 and 2001. The average COPS grant reduced burglaries by 2.2 %, auto thefts by 3.3 %, robberies by 5 %, murders by 3.2 %, and assaults by 3.6 %. The authors showed that although the total grant amount received over the 1994-2002 period was correlated with the size of the police force and crime levels in 1993, there was no correlation between the timing of the receipt of the grants and prior crime trends. To better understand what led to the seemingly random allocation of COPS funds over time, Evans and Owens supported their empirical findings with qualitative evidence gathered through interviews with representatives of police agencies. Those interviews revealed that police agencies faced low barriers to apply and a simple application process. Once an agency received a grant, subsequent grants were awarded with minimal paper work. Furthermore, the disbursement of the requested funds was made in an arbitrary way, and in some instances, the COPS office actively solicited

grant applications.

Evans and Owens (2007) used the COPS grants as an instrument for changes in the size of the police force in a study designed to estimate the impact of police force size on crime rates. In this study, I take their findings one step further and use the COPS grants as an instrument for crime rates. Two sets of arguments justify this step. First, as in any instrumental variable design, the 2SLS estimates in Evans and Owens (2007) are generated by dividing two causal effects: the effect of the COPS grants on crime rates (their reduced-form estimate) over the effect of the COPS grants on the size of the police force (their first-stage estimate). Here, I extrapolate their reduced-form findings, which show a causal effect of the COPS grants on crime, and use that relationship as my first-stage equation. To verify that this relationship holds in my sample, in Table 2, I show that the receipt of the grants led to substantial reductions in crime rates.¹⁰

Secondly, to assess the plausibility of the exclusion restriction assumption, in Figures A2 to A7 in the Appendix, I examine how several school district outcomes changed during the time window that spans from 3 years before the COPS grants were received to 3 years after they were received. These outcomes include violent crime rates in the district, district-wide achievement, revenue that districts collected from property and income taxes, instruction-related school expenditures, teacher salaries, third- and eighth-grade enrollment in the schools in the district, socio-economic composition of schools in the district, and state-level incarceration rates. The conclusion that emerges from these additional analyses is that the COPS grants increased achievement levels in the district through their impact on crime rates, but they did not change other attributes of the district that are directly or indirectly linked to achievement. While circumstantial, this evidence provides compelling support for the exclusion restriction assumption needed in the 2SLS estimation.¹¹

¹⁰Prior studies of the COPS program have showed that most police officers that were hired through the grants remained in the police force over the long run (Evans and Owens, 2007). Given that this study is focused on long-term impacts on achievement, I use the cumulative number of police officers that had been hired and retained up to the time when a birth cohort was 0-6 years old.

¹¹Prior work has documented a correlation between crime and the residential choices of families of different groups (Dugan, 1999; Ellen et al., 2017; Xie and McDowall, 2014). These studies rely on correlational data,

The system of equations in the 2SLS estimation takes the following form:

$$Crime_{sc} = \pi_1 COPS_{sc} + \mathbf{S}'_s + \mathbf{C}'_c + \epsilon_{sc} \quad (2)$$

$$Y_{sc} = \pi_2 COPS_{sc} + \mathbf{S}'_s + \mathbf{C}'_c + \nu_{sc} \quad (3)$$

In both equations, $COPS_{sc}$ is the number of police officers per 100,000 residents that had been hired through the COPS program by the municipal police department operating in district s when birth cohort c was 0-6 years old, Y_{sc} is eighth-grade achievement in ELA and Mathematics in school district s for birth cohort c (measured in standard deviations of the national distribution), $Crime_{sc}$ is the log average violent crime rate per 100,000 residents in school district s when birth cohort c was 0-6 years old, \mathbf{S}'_s is a set of school district fixed effects, and \mathbf{C}'_c is a set of birth cohort fixed effects. Standard errors are clustered by school district.

Equation (2) is the first-stage equation and estimates the impact of the COPS grants on the violent crime in the district, π_1 . Equation (3) is the reduced-form equation and estimates the impact of the COPS grants on the eighth-grade achievement in the district, π_2 . The 2SLS estimate of the effect of changes in violent crime on eighth-grade achievement, δ_{2SLS} , is obtained by dividing the reduced-form estimate over the first-stage estimate ($\delta_{2SLS} = \pi_2/\pi_1$).

Table 2 reports first-stage estimates for all violent crimes combined and for each of the three types of crime individually. Column 1 shows that, in a school district with 100,000 residents, the hiring of one additional police officer through the COPS program led to a 1.3 % decline in the violent crime rate, a .7 % decline in the murder rate, a 1.2 % decline in the aggravated assault rate, and a 1.5 % decline in the robbery rate. In all specifications, a Wald test on the excluded instrument yields an F-statistic above 10, which meets the criterion

and it is difficult to extract any benchmarks from them. It is also important to keep in mind that my sensitivity analyses in Figure A6 do not focus on changes in crime rates; they focus on changes in the COPS grants and the extent to which they changed student composition of the school district. I find no clear evidence of that being the case.

suggested by Stock and Yogo (2005) to avoid problems associated with weak instruments. Table A1 in the Appendix shows the mean and standard deviation of the change in violent crime rate at ages 0-6 from the 1996 to the 2002 birth cohort for three sets of school districts: school districts that did not experience any change in COPS grants between the 1996 and 2002 cohorts, school districts with a below-median (and greater than zero) change in COPS officers between the 1996 and 2002 cohorts, and school districts with an above-median change in COPS officers between the 1996 and 2002 cohorts. The table shows that in districts that experienced a change in COPS hiring between the 1996 and 2002, crime rates declined in a way that was monotonic with the growth in COPS officers.

Results

Before moving to the regression results from the difference-in-differences estimation, I show how achievement correlates with crime across districts, ignoring changes over time (i.e., averaging district-level measures of crime and achievement over the seven birth cohorts). Figure 2 shows the cross-sectional association between the violent crime rate in the district when birth cohorts were 0-6 years old and the ELA and Mathematics achievement by eighth grade. The scatterplots reveal a strong, negative correlation between crime experienced at ages 0-6 and ELA and Mathematics achievement by the end of eighth grade. On average, school districts with a violent crime rate one standard deviation above the mean show a performance level in ELA that is .51 standard deviations below the national mean ($R^2 = .26$) and a performance level in Mathematics that is .49 standard deviations below the national mean ($R^2 = .25$). These negative associations hold when controlling for observable characteristics of the school districts.¹²

The next set of analyses estimates impacts of changes over time in the violent crime rate in the school district using the OLS and 2SLS difference-in-differences estimation strat-

¹²These controls are obtained from the 2000 Census and include % non-Hispanic white, % non-Hispanic black, % Hispanic, % foreign-born, % unemployed, % families with income below the poverty line, and median household income (in 2000 USD).

egy outlined above. Results reported below take advantage of the group-specific achievement measures available in the SEDA data, and they show effects for all students in the district combined, by racial/ethnic group, and by gender.¹³

Effects of Violent Crime by Race and Gender

Table 3 shows OLS difference-in-differences estimates for all students pooled and by racial/ethnic group. As a reminder, crime rates enter the model log transformed. The interpretation that follows will translate the size of the estimated regression coefficients as changes in achievement for each 10 % decline in crime rates. On the basis of these estimates, the overall ELA achievement in the district increased by .01 standard deviations for each 10 % decline in violent crime, without showing much heterogeneity across racial/ethnic groups.

Table 4 shows 2SLS difference-in-differences estimates for all students pooled and by racial/ethnic group. The overall ELA achievement in the district increased by .03 standard deviations for each 10 % decline in violent crime. In other words, in a district of 100,000 residents, the .03 standard deviation gain in ELA performance was caused by a decline in 88 violent crimes induced by the hiring of around 8 COPS officers, according to the first-stage estimates in Table 2. Models that estimate the effect on Mathematics show slightly smaller magnitudes that are not statistically significant.

Models that estimate impacts by racial/ethnic group show that the district-wide impact is driven by changes in achievement among black students. A 10 % decline in violent crime experienced between ages 0-6 led to a .03 standard deviation gain in ELA achievement by the end of eighth grade for black students. For Hispanic and white students, the magnitudes of such impact are a statistically non-significant .03 and .02 standard deviation gain, respectively. Models that estimate impacts on Math achievement show smaller and

¹³In the SEDA data, the measure of achievement for all students combined is constructed from the test scores of students of all racial and ethnic groups in the school district, which include more groups than the three being considered here. The choice of reporting disaggregated results for black, Hispanic, and white children, but not for others, is because in some districts the number of students of other racial/ethnic minorities is too low to yield reliable estimates of their achievement.

statistically non-significant magnitudes. The magnitudes of the coefficients for Math for the three racial/ethnic groups follow a pattern that is similar to that in ELA models (i.e., a larger effect size among black students).

Since crime rates are markedly higher in predominantly black districts, one possible explanation for the larger effects among black students is that the absolute changes in crime rates in predominantly black districts are larger than the absolute changes in predominantly white districts. In such scenario, a 10 % drop in the violent crime rate means comparing a very different absolute change when estimating results by race. To assess the extent to which these differences in absolute changes in crime rates are driving the differences in effects reported in Table 4, I divide the sample of school districts into low- and high-crime districts, based on whether the violent crime rate in 1996 was below or above the sample median, and estimate race-specific 2SLS models in each of these two subsamples. Results from these models are shown in Figure 3. When comparing the effect sizes by race within high-crime districts, the racial differences reported before still remain. For black and Hispanic students in high-crime school districts, each 10 % decline in the violent crime rate increased ELA achievement by .03 standard deviations. For white students in high-crime districts, a comparable 10 % decline in the violent crime rate led to a statistically non-significant increase in ELA achievement by .02 standard deviations. This suggests that differences in absolute changes in crime rates are not the explanation for the larger impacts among black students.¹⁴

Figure A8 in the Appendix shows OLS estimates for ELA by race when violent crime is measured in one-year windows between the ages of 0 to 13. On the basis of these estimates, the eighth-grade performance of children seems to be more impacted by exposure to violent crime at ages 4-8. This pattern is consistent with findings by Sharkey et al. (2014), who

¹⁴Although the magnitudes of the coefficients are larger for black students than for white students, these differences are not large enough to generate statistically significant impacts on white-black achievement gaps. The SEDA data includes estimates of racial/ethnic gaps for each school district and birth cohort. In Table A2 in the Appendix, I use these racial/ethnic gaps as outcomes in the 2SLS regressions. Results from these models suggest a positive impact of changes in crime rates (i.e., gaps narrowed as crime rates declined), but these effects are statistically non-significant.

document significant negative effects of acute exposure to violence on test scores among elementary school students (in grades 3, 4, and 5) but no effect on middle school students (in grades 6, 7, and 8). The OLS estimates in Figure A8 cannot be given a causal interpretation, but the pattern revealed in the three plots is nonetheless informative. Unfortunately, I cannot estimate 2SLS models beyond the age of 6 because of a change in how the COPS grants were distributed after 2008, the year when the 2002 birth cohort was 6 years old. After 2008, the COPS program was redesigned and grants were allocated following a different rule. Police departments that applied were scored and ranked by the COPS office, and that ranking determined the allocation of grants. This change in the allocation of grants makes the use of post-2008 data inadequate in a difference-in-differences setting like the one being used here.

Tables 5 and 6 show OLS and 2SLS difference-in-differences estimates by gender. On average, boys experienced larger gains in ELA and Mathematics as crime rates fell. On the basis of the 2SLS estimates, ELA and Mathematics achievement of male students increased by .03 standard deviations for each 10 % decline in violent crime rate. For the same change in the violent crime rate, females experienced a statistically non-significant gain of .02 standard deviations in ELA and no change in Mathematics.¹⁵

Effects by Type of Crime

So far, the analyses have focused on estimating the effect of changes in the violent crime rate in the school district. The aggregated violent crime index is used here to capture changes in the levels of neighborhood violence that surrounds children in their day-to-day lives. In this section, I use the rates of homicides, aggravated assaults, and robberies to estimate the impact of each of them individually on ELA achievement. Estimating effects for each of the three types of crime that compose the violent crime index is valuable from a methodological standpoint because it enables the assessment of potential measurement error issues. The violent crime index is dominated by aggregated assaults and robberies, which are

¹⁵In models that use SEDA estimates of gender gaps as outcomes (Table A2 in the Appendix), the female-male gap in Mathematics is statistically significant.

likely to be influenced by discretionary ways of measuring and reporting them across police departments. Therefore, estimating the effect of changes in the homicide rate alone, which is less vulnerable to measurement error, will yield more reliable estimates. A second reason to focus on homicides is to align this study with prior work that has documented acute effects of exposure to homicides on cognitive assessments (Sharkey, 2010; Sharkey et al., 2014).

Figure 4 shows 2SLS estimates of the impact of each of the three types of violent crimes on ELA by race and gender. Homicides show the largest relative impact on achievement. For a 10 % decline in the homicide rate, the ELA achievement of black and Hispanic children increased by .06 and .05 standard deviations, respectively. Among males, the impact on ELA achievement of a 10 % decline in the homicide rate was a .11 standard deviation gain. Males also experienced a .07 standard deviation gain in Mathematics achievement for a 10 % decline in the homicide rate.

If we take the homicide estimates from Figure 4 as the most reliable ones and consider the change in the homicide rate at ages 0-6 from the 1996 to the 2002 cohorts, a 19 % drop, we find that such average change in the homicide rate translated into a .11 standard deviation gain in ELA achievement for black students and a .10 standard deviation gain in ELA achievement for Hispanic students. Assuming that achievement grows at an average of .3 to .5 standard deviations per school year in elementary school grades, a 19 % decline in the homicide rate represented a gain in 2-3 months of instruction for black and Hispanic children, approximately.¹⁶ Extrapolating these findings to the period that goes from 1992 to 2012, a time when the national homicide rate fell by approximately 50 %, being born 20 years apart and experiencing markedly lower levels of violence meant having benefited from the equivalent to 5 to 8 additional months of instruction.

¹⁶The range of .3-.5 standard deviations in growth per school year captures most of the estimates that the literature in education has generated up to this point. School years are assumed to have 9 months of instruction.

Interpreting the Reduced-Form Estimates

Up to this point, the interpretation of regression coefficients has focused on the second-stage results, which provide estimates of the local average treatment effect of crime on achievement. In most instrumental variable analyses, the interpretation of results would end here. However, given the nature of the instrument being used here—federal dollars spent in community policing, the reduced-form estimates have meaningful policy implications. Specifically, π_2 will capture the causal effect of hiring one additional police officer through the COPS grants on school achievement in the district. Knowing the average cost of hiring one police officer, we can estimate the return in standard deviations of each dollar spent through the COPS program.

The reduced-form estimates show that, in a school district with 100,000 residents, hiring and retaining one additional police officer increased the ELA achievement of students in each cohort in the district by .005 standard deviations (see Figure A2 in the Appendix). The average size of a birth cohort attending public schools in a school district with 100,000 residents is 1,597 children.¹⁷ If we round this figure up to 1,750 to include students in charter schools, we get that in a district with 1,750 students in each cohort, hiring one police officer through the COPS grant raised the average eighth-grade ELA performance of the birth cohort by .005 standard deviations. Considering that the average cost of hiring one police officer through the COPS grants in the sample of school districts in the analysis was \$151,639 (in 2015 USD), we get that an average increase in COPS spending of \$86 per pupil increased the achievement in the district by .005 standard deviations. Equivalently, an average increase in COPS spending of \$1,720 of per pupil increased the ELA achievement by .10 standard deviations. Lafortune et al. (2018) estimate that an increase in state aid per pupil per year of \$622 and an increase in total revenue per pupil per year of \$424 following school finance reforms also raised achievement in the district by .10 standard deviations. The return of

¹⁷This figure corresponds to the average enrollment per grade in years 1994-2008 in the set of 813 school districts included in the sample.

the COPS program appears small when compared to the return of the education reforms examined by Lafortune et al. (2018); however, if we think of the increase in achievement documented here as an unintended consequence of a policy aimed at making neighborhoods safer without targeting student outcomes directly, the return of the COPS program is sizable.

Discussion

Although violent crime rates in America still remain higher than in most developed countries (United Nations Office on Drugs and Crime, 2017), the decline in violence that began in the early 1990s represents a major improvement in the quality of life of Americans. While much has been written about the causes of the crime decline (Levitt, 2004; Zimring, 2006), our understanding of its consequences for individuals and communities is more limited. This study is an attempt to fill this gap. It estimates the impact of declining crime rates on the educational achievement of seven birth cohorts who entered the school system when the violent crime rate in their school districts was markedly different.

The oldest cohort of children in this study was born in 1996, when the national violent crime rate was at 636 crimes per 100,000 residents. The youngest cohort was born in 2002, when the national violent crime rate was 494, a 23 % decline from the 1996 level (United States Department of Justice, 2015). Being only seven years apart meant living through childhood and adolescence with a lower risk of being victimized in the streets and experiencing the trauma and stress associated with living in violent environments. When comparing the achievement at the end of eighth grade of children born between 1996 and 2002, we see that experiencing a 10 % decline in violent crime raised the district-wide performance in ELA of an entire birth cohort by .03 standard deviations. Analyses by race/ethnicity show that the district-wide improvement in achievement that took place as crime rates fell is driven by the gains that accrued to black children. These findings are consistent with existing evidence from studies that documented that the acute effect of exposure to homicides on students' performance is larger among black students and in predominantly black schools

(Sharkey, 2010; Sharkey et al., 2014; Gershenson and Tekin, 2017). The larger effects among black and Hispanic students make sense if we consider that their neighborhoods, which have higher levels of concentrated violence on average (Morenoff and Sampson, 1997; Peterson and Krivo, 2010; Sampson et al., 1997), experienced the largest declines in crime in the 1990s and 2000s (Friedson and Sharkey, 2015).

An important finding emerging from this study is the larger effect of violence among boys. On the basis of the 2SLS estimates in Table 6, the achievement gap between female and male students closed by .03 standard deviations in Mathematics for a 10 % decline in the violent crime rate. While girls are also exposed to community violence and forced to develop strategies to navigate threatening school and street environments (Jones, 2009), existing ethnographic accounts show that the most severe consequences of neighborhood violence are experienced by young, minority men (Anderson, 2000; Harding, 2010). From this perspective, it makes sense that the alleviation of the stress and trauma associated with having to navigate violent spaces translated into larger gains among boys.

Focusing on the coefficient magnitudes, the size of these effects may appear small. However, it is worth remembering that these improvements in achievement are averaged over all students in the school district. These estimates imply that the effect might be larger for children living in neighborhoods where crime was more concentrated and where the crime drop was felt more intensely (Friedson and Sharkey, 2015). Similarly, data limitations do not allow taking a longer term view and comparing, for example, the achievement of children born in the late 1980s and children born in the early 2000s. These two sets of children lived through school years in vastly different neighborhood and school environments in terms of levels of violence. If we are willing to extrapolate the 2SLS estimates obtained here to the 20-year period that goes from 1992 to 2012, the average change in the homicide rate during that time, approximately a 50% decline, represents that children born in 2012 will benefit from the equivalent to 5-8 months of additional instruction by the end of eighth-grade because of the drop in neighborhood violence.

The evidence on ELA achievement is clear and strong, but the effect of violent crime on Mathematics is inconclusive. All point estimates for Mathematics are in the same direction than those in ELA models, but their magnitudes are smaller and, in some models, statistically non-significant. This pattern is consistent with findings from other studies of violence and student outcomes (Sharkey, 2010; Sharkey et al., 2014). These studies have suggested that performance in mathematics and reading assessments may be explained by different self-regulatory mechanisms that interact differently with violence-related stressors (Liew et al., 2008). Children suffering from the trauma and stress associated with neighborhood violence may find it harder to maintain the level of attention and concentration necessary in reading assessments in which the different parts of the test are often interconnected, but they may find it easier to stay focused during mathematics assessments in which test items can be tackled individually. One additional explanation for the difference in ELA and Mathematics estimates is that the learning of literacy skills relies more on the support and resources that children find at home than the learning of mathematics skills does (Griffin and Morrison, 1997). The disruption that violence causes in the neighborhood is likely to enter the home environment if parents become anxious about their children being victimized or if children are exposed to the constant sound of sirens, for example, hindering the learning of reading skills that take place at home.

The findings from this study add to a growing body of work showing that economic opportunity varies substantially by location (Chetty et al., 2014), and they suggest that the effect of crime on economic mobility documented in previous studies operates, in part, through effects on educational achievement (Sharkey and Torrats-Espinosa, 2017). If places, rather than people living in them, are responsible for the differences in economic mobility across metropolitan areas (Chetty and Hendren, 2018), making places safer can generate long-term social returns that extend beyond the most immediate and direct benefits of reducing community violence. More broadly, these findings provide additional evidence on the role that violence plays in shaping the developmental trajectories of children, and they

reinforce the idea that understanding differences in academic achievement requires evidence on what happens inside schools as well as what happens outside schools.

The most important limitation of this study is that it provides no evidence on the mechanisms driving the improvement in achievement as crime rates fell. The supplementary analyses in the Appendix show that the COPS funds did not change school resources and that the effects are not driven by changes in the economic and racial composition of school districts over time. It is unclear, however, whether children born in the 2000s did better because they were able to stay more focused on school as their surroundings became safer, or because safer streets meant that parents were more willing to enroll them in extra curricular activities that furthered their development, for example. Given the age when changes in crime rates are measured, at ages 0-6, it is likely that an important part of the explanation has to do with how parents responded to crime changes in the neighborhood. Future research that surveys children about their perceptions of safety and parents about their strategies to shield children from street crime can help unpack these mechanisms.

The discussion of the consequences of the crime decline cannot ignore the costs of such change. A shift toward more aggressive forms of policing and soaring incarceration rates have disrupted the lives of minority youth as much as street violence did in the 1980s and early 1990s. More police in the streets cannot be the only response to confront community violence, and the reduced-form findings do not mean that to close achievement gaps we need more police in the streets. The use of the COPS grants as an instrumental variable is just a methodological tool to recover casual estimates from a policy shock that reduced crime rates. The policy debate should be around strategies to make neighborhoods safer. Giving more resources to police departments so that they can engage and partner with community organizations and provide effective responses to communities' needs is just one of the many possibilities. Importantly, law enforcement agencies should be held accountable so that they carry their jobs with fairness and without engaging in discriminatory practices. This accountability requirement is of crucial importance in light of recent qualitative and

quantitative evidence showing the negative effects of policing on minority youth (Rios, 2011; Legewie and Fagan, 2019).

Figures and Tables

Figure 1: Eighth-Grade Achievement, By Race, Cohorts 1996-2002

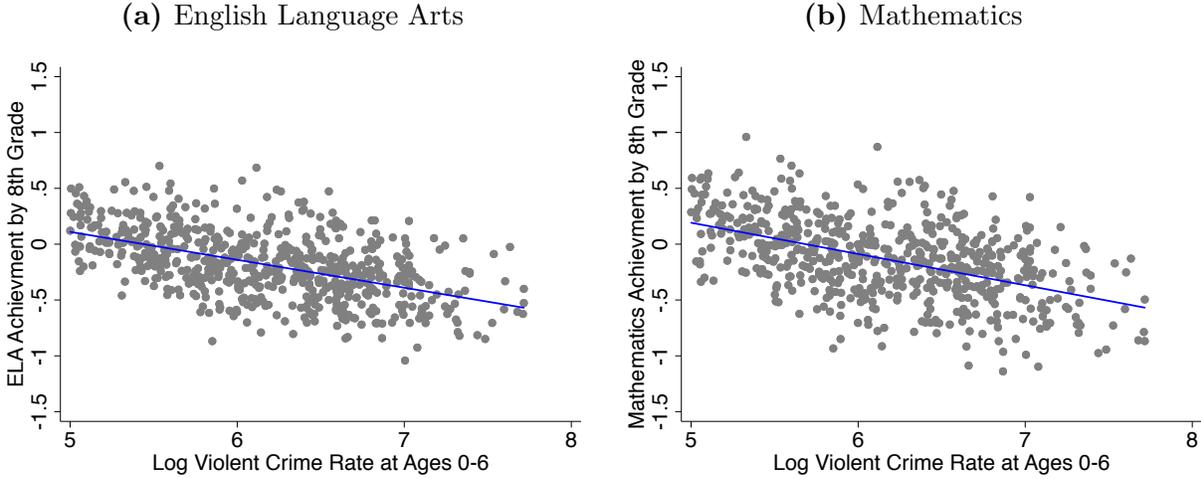

Notes: Achievement data are from the district-level estimates from the SEDA data (Reardon et al., 2016b). Each bar shows the average 8th grade achievement across all school districts in the sample (N=813) for a given birth cohort and racial/ethnic group.

Table 1: Average Crime and COPS Rates at Ages 0-6, By Cohort

	Birth Cohorts						
	1996	1997	1998	1999	2000	2001	2002
<i>Violent Crime Rate</i>							
All Violent	879.44 (421.70)	826.82 (393.29)	795.97 (390.78)	785.37 (376.12)	770.63 (368.83)	803.98 (368.35)	799.90 (360.02)
Murder	13.06 (7.15)	12.04 (6.47)	11.85 (6.52)	11.60 (6.48)	10.02 (5.57)	11.55 (6.19)	10.64 (5.62)
Agg. Assault	528.15 (269.32)	497.44 (245.44)	484.14 (236.09)	478.27 (220.73)	468.72 (217.29)	462.08 (206.25)	464.41 (194.14)
Robbery	338.23 (195.18)	317.33 (185.02)	299.98 (178.02)	295.50 (173.49)	291.89 (171.81)	330.35 (184.04)	324.85 (188.97)
<i>COPS Grants</i>							
Officers	16.06 (9.05)	16.98 (10.39)	17.84 (10.77)	21.10 (12.34)	27.78 (19.10)	27.96 (18.86)	28.15 (18.71)
Grant Amount	2.21 (1.21)	2.39 (1.36)	2.59 (1.46)	2.99 (1.60)	3.68 (2.14)	3.71 (2.10)	3.74 (2.08)

Notes: The crime data are from the FBI's UCR Program, and the COPS data are from the Department of Justice's COPS Office. Crime reports and COPS grants from local police agencies are assigned to census incorporated places (i.e., cities and towns) using the Law Enforcement Agency Identifiers Crosswalk from the National Archive of Criminal Justice Data, and places are crosswalked to school district boundaries in the SEDA data by identifying the place whose centroid falls inside the boundaries of a given school district. Crime rates are in number of crimes per 100,000 residents when a birth cohort was 0-6 years old. COPS grants are measured in number of officers hired per 100,000 residents and in millions of dollars per 100,000 residents (in 2010 USD) when a birth cohort was 0-6 years old.

Figure 2: Cross-Sectional Relationship Between Crime and Achievement

Notes: Achievement data are from the district-level estimates from the SEDA data (Reardon et al., 2016b), and crime data are from FBI’s UCR Program. Each dot represents a school district (N=813), and it measures the log mean violent crime rate in the school district at ages 0-6 averaged across all seven birth cohorts (1996-2002) and the mean 8th grade achievement in the school district averaged across all seven birth cohorts. The measures of achievement are estimated by combining students of all racial/ethnic groups together.

Table 2: First-Stage Estimates, Ages 0-6

	(1) All Violent	(2) Murder	(3) Aggr. Assault	(4) Robbery

Figure 4: 2SLS Estimates, By Type of Crime

Notes: Point estimates and 95 % confidence intervals are obtained from 2SLS regressions analogous to the ones used in models reported in Tables 4 and 6. Standard errors clustered are by school district. All models include school district fixed effects, cohort fixed effects, and precision weights. Crime rates are in number of crimes per 100,000 residents in the district (averaged across ages 0-6 and log transformed). ELA and Mathematics achievement are computed at the end of 8th grade and measured in standard deviations of the national distribution.

Appendix A: The COPS Instrument

Hiring of Officers Outside of the COPS Program

Figure A1 shows the number of police officers per 100,000 residents in the school district that were on active duty in a given year in the sample of 813 school districts. The dashed line and the right y-axis show officers that had been added to the police force through the COPS program. The solid line and the left y-axis show officers that had been added through a hiring process different than the COPS program. The number of police officers per 100,000 residents that were hired through the COPS program increased from 12 in 1996 to 25 in 2008, whereas the number of police officers per 100,000 residents that were hired outside of the COPS program increased from 179 in 1996 to 199 in 2008. In absolute terms, fewer officers were added through the COPS program, but in relative terms, the growth in COPS officers was more rapid during this period. The size of the COPS police force grew by 108 %, whereas the size of the non-COPS police force grew by 11 %.

Changes in Crime Rates By Changes in COPS Grants

Table A1 splits the sample of school districts into three groups based on the change from the 1996 to 2002 birth cohorts in the rate of officers hired through the COPS program at ages 0-6. The first column are districts with no change in COPS officers from 1996 to 2002, the second column are districts with above zero but below-median change in COPS officers from 1996 to 2002, and the third group are districts with above-median change in COPS officers from 1996 to 2002. Each column shows the mean and standard deviation of the change in the violent crime rate at ages 0-6 from the 1996 to the 2002 birth cohort (in %). Comparing rates of change in the violent crime rate across columns, we can see that the decline in violence was larger in districts where the hiring of COPS officers was also higher.

Trends in Crime and Achievement Before and After the COPS Grants

Figures A2 to A7 are a series of event studies examining how different district-level outcomes changed before and after the receipt of the COPS grants. The coefficient plots are meant to represent trends in the corresponding outcome three years before the COPS grants were received and up to three years after. In practice, this is accomplished by adding lags and leads to the COPS measure relative to the measure of the outcome in the district and estimating the difference-in-differences model. For example, the point estimate on the far left in Figure A2a shows the effect of the COPS instrument on violent crime when the instrument leads the crime measure by 3 years. The point estimate on the far right shows the effect of the instrument on violent crime when the instrument lags the measurement of crime by three years. Before the officers were hired, districts followed similar crime and achievement trends (estimates -3 to -1 in the x-axis), which supports the common trends assumption needed to recover a causal effect from the difference-in-differences estimate. After the hires took place, we see a reduction in crime and an increase in achievement that lasted up to 3 years after the hires (estimates 0 to $+3$ in the x-axis). Each police officer hired through the grants led to a 1.3 % reduction in violent crime and to a .005 standard deviation increase in ELA achievement in the district. Figure A2b follows the same logic and shows trends in achievement before and after the receipt of the COPS grants. As it can be seen, districts that were set to receive a COPS grant followed a similar trend in ELA achievement in the three years prior to the receipt of the grant than districts that did not receive any grants. After the grants were received, ELA achievement increased relatively more in districts that hired more police officers through the COPS program. For an average increase in the number of police officers hired through the COPS grants per 100,000 residents at ages 0-6 of 12, ELA achievement at the end of eighth grade increased by .05 standard deviations.

In the next section, Figures A3 to A7 show changes before and after the COPS grants were received for a number of district characteristics. As before, these figures are event studies showing coefficient plots from separate regressions in which lags and leads have been

added to the COPS measure. These lags and leads span from three years prior to the receipt of the grants up to three years after.

Trends in School Resources Before and After the COPS Grants

In Figure A3, I use data at the school district level from the Local Education Agency Finance Surveys of 1994 to 2008 from the National Center for Education Statistics to examine trends in revenue that school districts collected through local property taxes and income taxes before and after the COPS officers were hired through the grants. The coefficient plots suggest that the COPS grants were not correlated with prior and posterior trends in revenue collection.¹ This indicates that high-income and affluent families were not moving at higher rates into districts that were expected to receive more COPS grants. It also suggests that these families did not move at higher rates into districts that had received more COPS grants. This evidence suggests that the improvement in achievement in districts that experienced declines in violence after the COPS grants were received was not driven by more affluent families moving into these districts.

Another explanation for the findings on crime and achievement could be that public schools received more resources as cities received COPS funds to hire police officers. One could imagine a scenario in which a city had allocated certain funds at the beginning of the fiscal year to hire police officers, but when the city received the COPS grant, those funds were reallocated to the public school system in the city. That would represent a violation of the exclusion restriction in the 2SLS estimation because the instrument would have an effect on achievement through a channel other than the reduction in crime rates. To assess this possibility, in Figure A4, I use data from the Local Education Agency Finance Surveys of 1994 to 2008 from the National Center for Education Statistics to examine trends in

¹The estimating equation corresponding to Figure A3 has the following form: $Y_{st} = \beta COPS_{st} + \mathbf{S}'_s + \mathbf{C}'_t + \epsilon_{st}$, where Y_{st} is the log revenue (in 2015 USD) per 100,000 residents in school district s in year t ; $COPS_{st}$ is the number of police officers per 100,000 residents hired through the COPS grants in school district s in year t ; and \mathbf{S}'_s and \mathbf{C}'_t are school district and year fixed effects. The sample includes the same 813 school districts used in the previous analyses. Changes in COPS grants and outcomes are measured year-to-year from 1994 to 2008.

school district expenditures and teacher salaries before and after the COPS grants. None of the point estimates reported in Figure A4 suggests that school districts increased their expenditures or teacher salaries in a way that was correlated with the COPS grants.²

Trends in Enrollment and Composition of Schools Before and After the COPS Grants

One limitation of the SEDA data is that they represent repeated cross-sections of districts over several school years (Reardon, 2018). As such, it is impossible to determine, for example, whether the children who started third grade in school year 2009-2010 were the same ones that were in eighth grade by school year 2014-2015. Students moving to other school districts or being retained in a grade will change the pool of students between third and eighth grade. Changes in the composition of the student body would not be problematic if they occurred at random. However, if the composition of birth cohorts changed with crime rates or the COPS grants, that would undermine the validity of the estimates. For example, if high-income families moved in greater numbers into school districts that became safer, that would increase the mean achievement in the district. Similarly, if low-income families stayed in school districts where violent crime had declined the least, the mean achievement in those districts would remain low.

To assess the extent to which the decline in crime induced by the COPS grants changed the composition school districts over time, in Figures A5 and A6, I use data at the school-level from the Public Elementary/Secondary School Universe Survey Data from the National Center for Education Statistics for years 1994 to 2008 to examine how enrollment and the socio-economic composition of schools in the district changed before and after the COPS officers were hired through the grants.³ Among other demographics, these data include

²The estimating equation corresponding to Figure A4 is analogous to that used in Figure A3 with Y_{st} representing the log of expenditures or salaries (in 2015 USD) per 100,000 residents in school district s in year t .

³Enrollment and demographic measures in the Public Elementary/Secondary School Universe Survey Data are at the school level. To be consistent with the rest of model specifications, I average these school-level measures across all schools in the district and estimate school district-level models. The estimating equation has the following form: $Y_{st} = \beta COPS_{st} + \mathbf{S}'_s + \mathbf{C}'_t + \epsilon_{st}$, where Y_{st} is the log of number of students in third grade, the log of number of students in eighth grade, the share of FRL-eligible students, the share

counts of students enrolled in each grade in the district, the total number of students enrolled in the district, the number of students with free and reduced-price lunch (FRL) eligibility,⁴ and the number of students of each racial/ethnic group. Figures A5 and A6 show that the COPS grants were not correlated with prior and posterior trends in third-grade enrollment, eighth-grade enrollment, share of students that were eligible for free and reduced-price lunch, share of black students, share of Hispanic students, and share of white students.

Trends in State-Level Incarceration Rates Before and After the COPS Grants

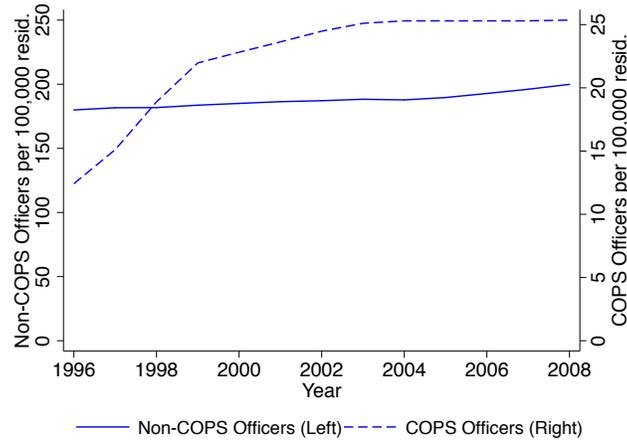

Lastly, in Figure A7, I use data at the state-level from Bureau of Justice Statistics to examine trends in incarceration rates before and after the COPS officers were hired through the grants. The coefficient plots show that the COPS grants were not correlated with prior and posterior trends in incarceration in the state, ruling out the possibility that the effects of the COPS grants on achievement runs through this channel.

The conclusion that emerges from Figures A2 to A7 is that the COPS grants increased achievement levels in the district through their impact on crime rates, but they did not change other attributes of the district that are directly or indirectly linked to achievement. While not definitive, this circumstantial evidence provides compelling support for the exclusion restriction assumption needed in the 2SLS estimation.

of black students, the share of Hispanic students, or the share of white students in school district s in year t . $COPS_{st}$ is the number of police officers per 100,000 residents hired through the COPS grants in school district s in year t ; and S'_s and C'_t are school district and year fixed effects. The sample includes the same 813 school districts used in the previous analyses. Changes in COPS grants, enrollment, and composition are measured year-to-year from 1994 to 2008. Measures of economic and racial composition are estimated for the entire district (i.e., pooling all students in grades K-12)

⁴ Using FRL eligibility status to measure the extent to which the economic composition in the district changed is an imperfect way of doing so, but given data limitations, it is the most common approach in the education literature. See, for example, Owens et al. (2016).

Figure A1: Police Officers per 100,000 Residents, 1996-2008

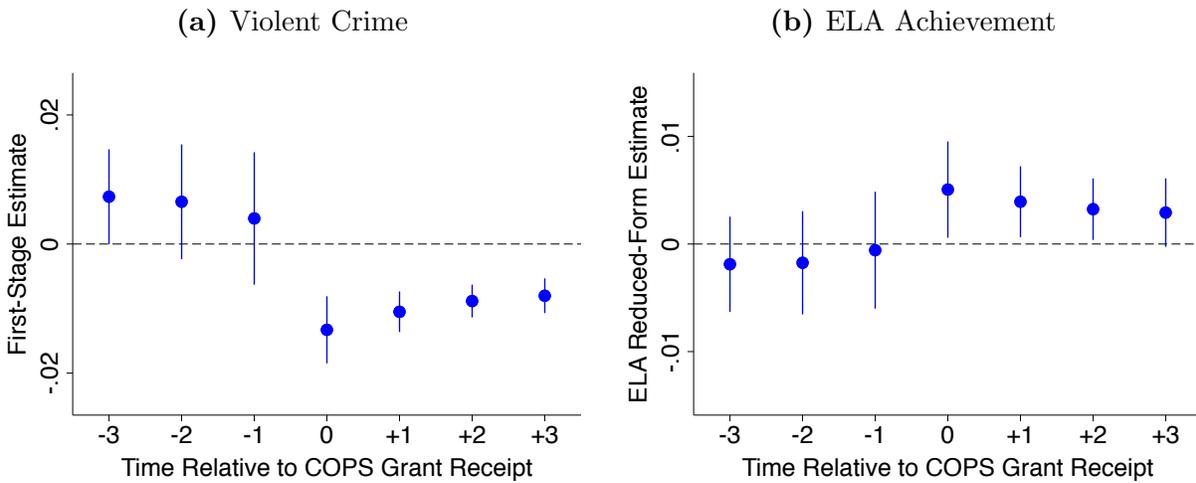

Notes: The dashed line and the right y-axis show officers that had been added to the police force through the COPS program. The solid line and the left y-axis show officers that had been added through a hiring process different than the COPS program.

Table A1: Change in Violent Crime (in %), By Change in COPS Officers, 1996-2002

	Change in COPS Officers (1996-2002)		
	$\delta = 0$	$0 < \delta < \text{median}$	$\delta \geq \text{median}$
% Change Violent	-2.05 (16.35)	-1.76 (19.00)	-10.03 (28.40)

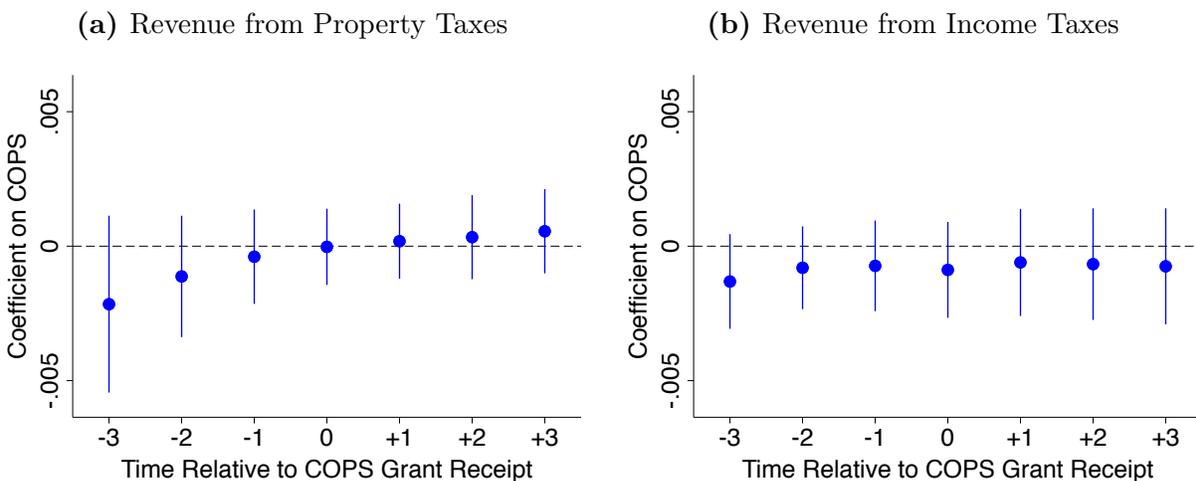

Notes: This table splits the sample of school districts into three groups based on the change from the 1996 to the 2002 birth cohorts in the rate of officers hired through the COPS program at ages 0-6. The first column are districts with no change in COPS officers from 1996 to 2002, the second column are districts with above zero but below-median change in COPS officers from 1996 to 2002, and the third group are districts with above-median change in COPS officers from 1996 to 2002. Each column shows the mean and standard deviation of the change in the violent crime rate at ages 0-6 from the 1996 to the 2002 birth cohort (in %). The sample includes the same 813 school districts used in the analyses.

Figure A2: Changes in Violent Crime and ELA Achievement Before and After the COPS Grants

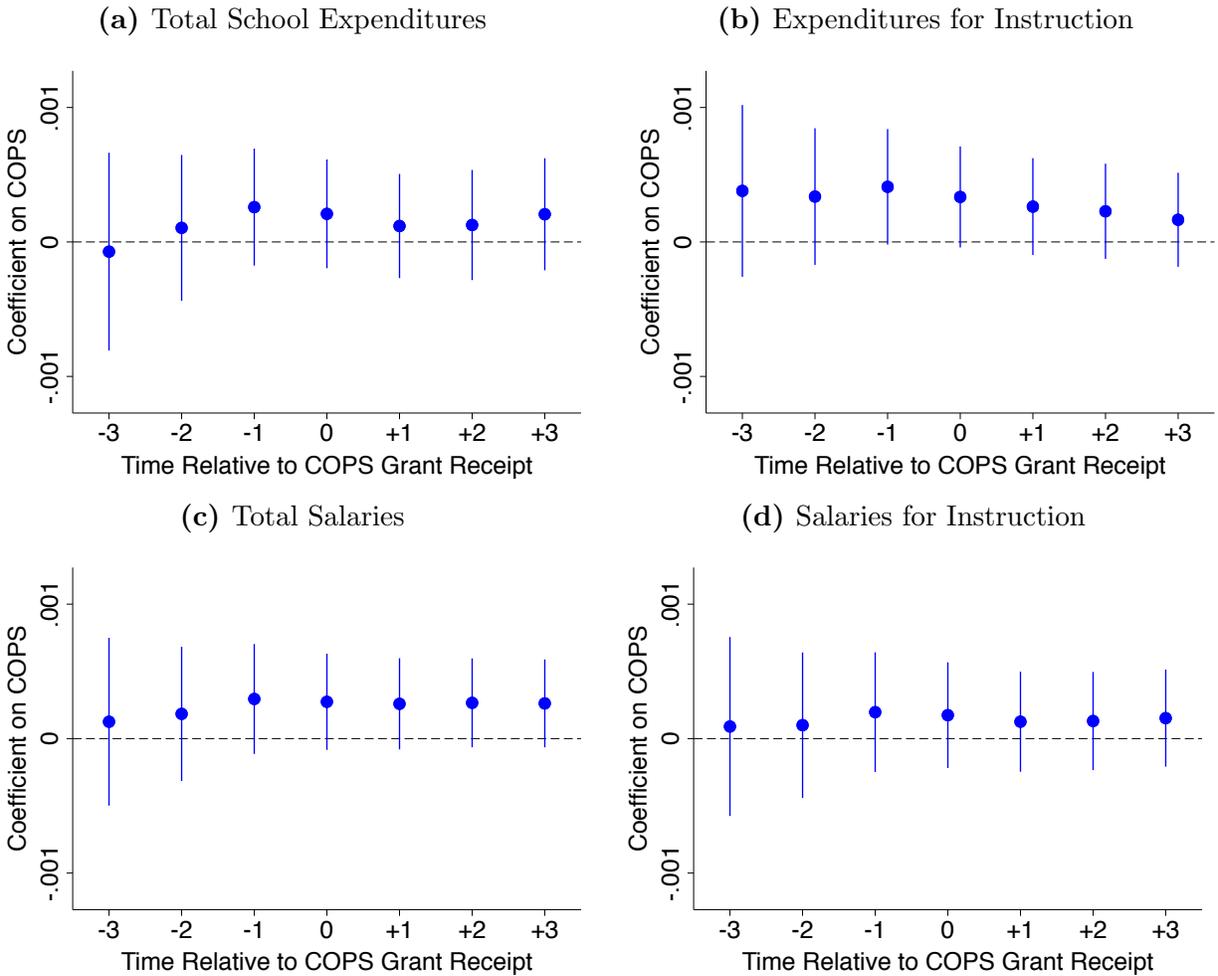

Notes: Each point estimate and 95 % confidence interval is obtained from a separate regression of the corresponding outcome on the COPS instrument. Each regression adds a lag or a lead to the COPS instrument (from -3 years to +3 years) relative to the outcome. COPS are in number of officers per 100,000 residents at ages 0-6. Violent crime rates are in number of crimes per 100,000 residents (log-transformed) at ages 0-6. ELA achievement is computed at the end of 8th grade and measured in standard deviations of the national distribution. The sample includes the same 813 school districts and 7 birth cohorts used in previous analyses. All models include school district fixed effects, cohort fixed effects, and precision weights.

Figure A3: Changes in School District Revenue Before and After the COPS Grants

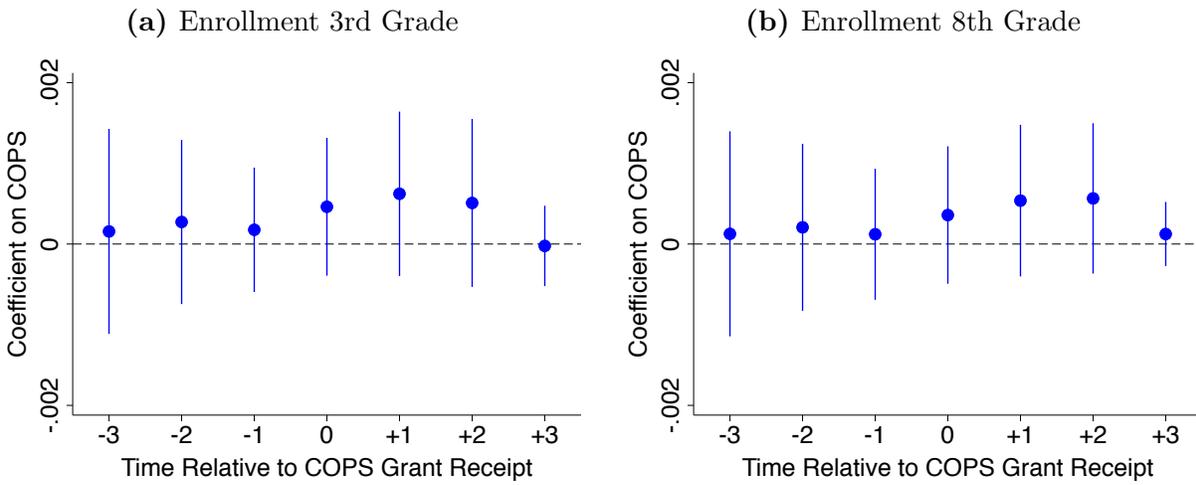

Notes: Each point estimate and 95 % confidence interval is obtained from a separate regression of the corresponding outcome on the COPS instrument. Each regression adds a lag or a lead to the COPS instrument (from -3 years to +3 years) relative to the outcome. COPS are in number of officers per 100,000 residents in the district. Revenue from property taxes and income taxes are in 2015 USD per 100,000 residents in school district (log transformed). COPS officers and school district revenue are measured year-to-year from 1994 to 2008. The sample includes the same 813 school districts used in previous analyses. All models include school district fixed effects and year fixed effects.

Figure A4: Changes in School Expenditures and Teacher Salaries Before and After the COPS Grants

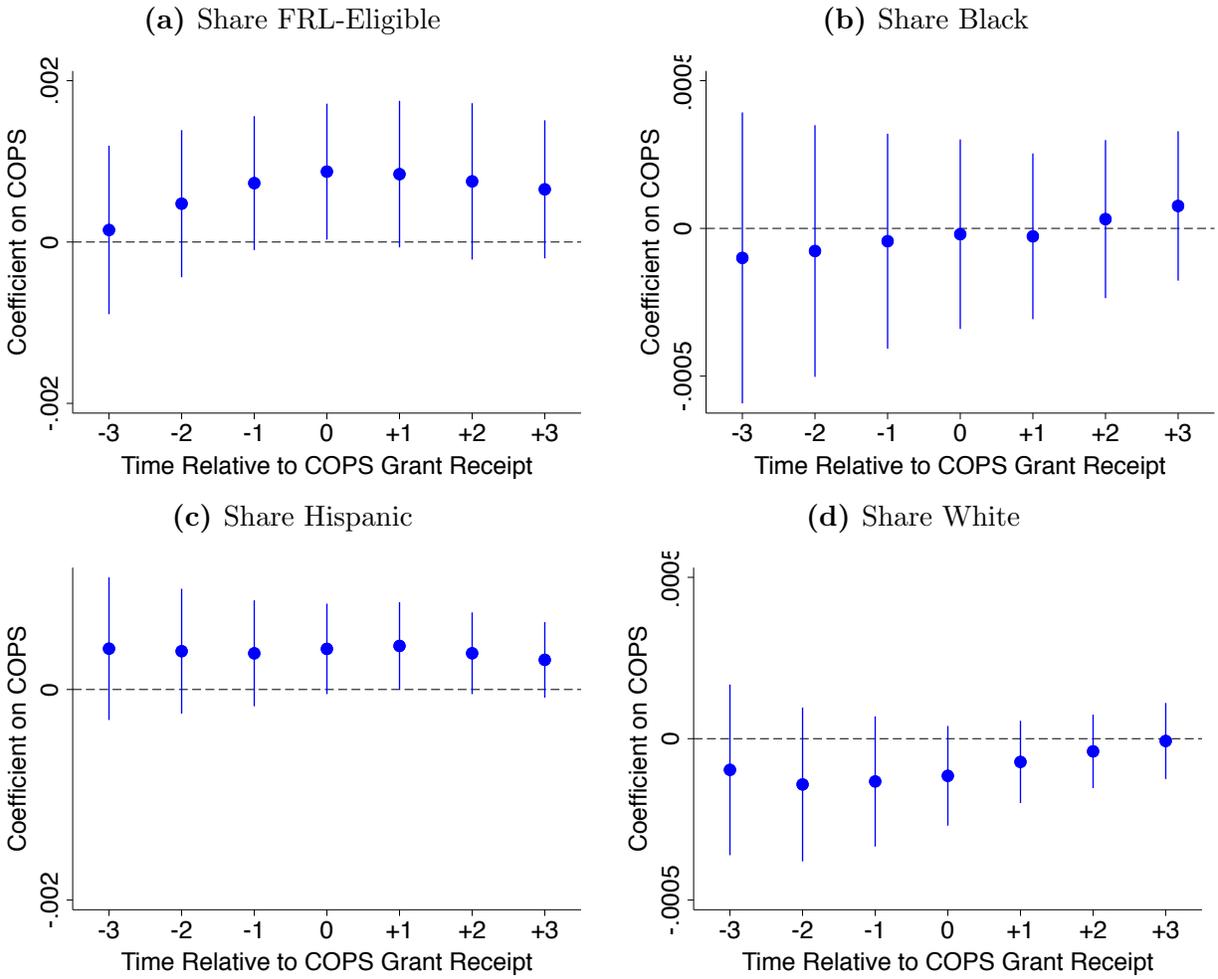

Notes: Each point estimate and 95 % confidence interval is obtained from a separate regression of the corresponding outcome on the COPS instrument. Each regression adds a lag or a lead to the COPS instrument (from -3 years to +3 years) relative to the outcome. COPS are in number of officers per 100,000 residents in the district. Expenditures and teacher salaries are in 2015 USD per 100,000 residents in school district (log transformed). COPS officers, expenditures and teacher salaries are measured year-to-year from 1994 to 2008. The sample includes the same 813 school districts used in previous analyses. All models include school district fixed effects and year fixed effects.

Figure A5: Changes in School District Enrollment Before and After the COPS Grants

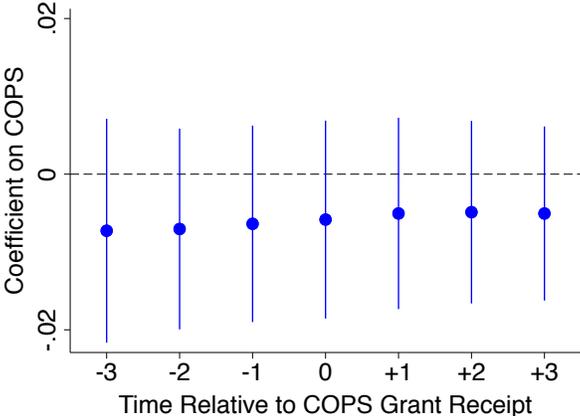

Notes: Each point estimate and 95 % confidence interval is obtained from a separate regression of the corresponding outcome on the COPS instrument. Each regression adds a lag or a lead to the COPS instrument (from -3 years to + 3y years) relative to the outcome. COPS are in number of officers per 100,000 residents in the district. Enrollment is the log number of students enrolled in the corresponding grade in all public schools in the district. COPS officers and enrollment are measured year-to-year from 1994 to 2008. The sample includes the same 813 school districts used in the previous analyses. All models include school district fixed effects and year fixed effects.

Figure A6: Changes in School District Composition Before and After the COPS Grants

Notes: Each point estimate and 95 % confidence interval is obtained from a separate regression of the corresponding outcome on the COPS instrument. Each regression adds a lag or a lead to the COPS instrument (from -3 years to +3y years) relative to the outcome. COPS are in number of officers per 100,000 residents in the district. Shares of FRL-eligible students, black students, Hispanic students, and white students are measured across K-12 grades. COPS officers and shares are measured year-to-year from 1994 to 2008. The sample includes the same 813 school districts used in previous analyses. All models include school district fixed effects and year fixed effects.

Figure A7: Changes in Incarceration Rates in the State Before and After the COPS Grants

Notes: Each point estimate and 95 % confidence interval is obtained from a separate regression of the corresponding outcome on the COPS instrument. Each regression adds a lag or a lead to the COPS instrument (from -3 years to + 3y years) relative to the outcome. COPS are in number of officers per 100,000 residents in the state. Incarceration rates are in number of persons in prison or jail per 100,000 residents in the state. COPS officers and incarceration rates are measured year-to-year from 1994 to 2008. The sample includes all US states except Alaska and Hawaii. All models include state fixed effects and year fixed effects.

Appendix B: Impact in Racial and Gender Gaps

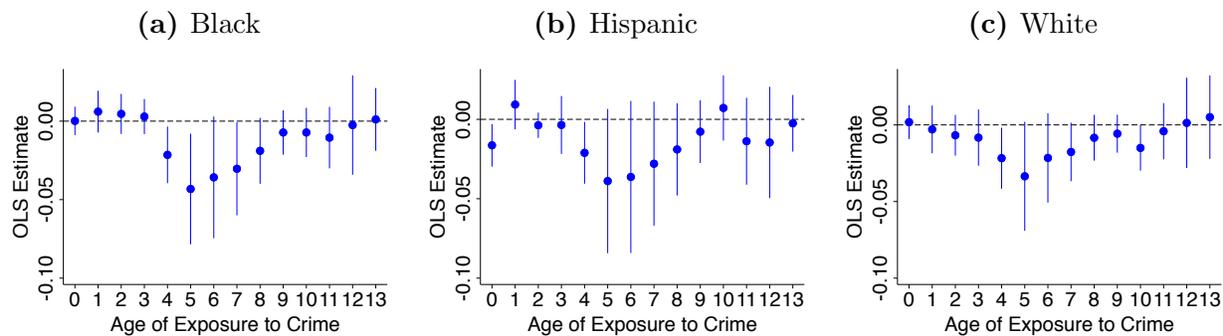

Table A2: 2SLS Estimates of Effect on Racial and Gender Gaps

Appendix C: OLS Estimates With Different Age of Exposure to Crime

Figure A8: OLS Estimates, ELA, By Age of Exposure to Crime

Notes: Each point estimate and 95 % confidence interval is obtained from a separate OLS regression of eighth-grade ELA achievement on violent crime rate. Each regression varies the age when the violent crime rate is measured for a given cohort, from 0 to 13 years old. Violent crime rates are in number of crimes per 100,000 residents (log-transformed). ELA achievement is computed at the end of 8th grade and measured in standard deviations of the national distribution. The sample includes the same 813 school districts and 7 birth cohorts used in previous analyses. All models include school district fixed effects, cohort fixed effects, and precision weights.
